SETUP

Different devices. The same Python.

Choose where Python will run

Colab

No local Python installation. Save a copy and upload the course support files.

Local JupyterLab

Install Python 3.12 or a newer supported stable release, plus JupyterLab. Download the course package.

Keep the choice simple

Use the route that works on your device. No GPU, paid plan or API key is required.

Colab uses a cloud runtime; local JupyterLab runs on your computer.

Choose Colab or the optional offline package

1

Choose the week

Open the current weekly notebook from its Colab link.

2

Save a copy

Save your own working notebook in Google Drive.

3

Run setup

Weeks 3–10 restore embedded support files. No ZIP upload or download.

4

Offline option

For local Jupyter, extract the optional package and keep its folders together.

Weeks 1–10 run directly in Colab without a support ZIP.

Windows: create a local environment

```
py -3 --version
py -3 -m venv .venv
$coursePy = ".\.venv\Scripts\python.exe"
& $coursePy -m pip install jupyterlab
& $coursePy -m jupyterlab --notebook-dir=learning_materials
```

1. Create .venv beside learning_materials/.
2. Use its Python for installation and launch.
3. Open the week’s notebook in JupyterLab.

Run these commands in PowerShell from the extracted repository root.

macOS or Linux: create a local environment

```
python3 --version
python3 -m venv .venv
.venv/bin/python -m pip install jupyterlab
.venv/bin/python -m jupyterlab --notebook-dir=learning_materials
```

1. Ubuntu is one Linux distribution.
2. Use .venv/bin/python for this project.
3. Keep system packages separate.

Run these commands in Terminal from the extracted repository root.

Colab: prepare your own working copy

1

Open the notebook

Use the current week’s Colab link.

2

Save your copy

Choose Save a copy in Drive before editing.

3

Run setup

Weeks 3–10 restore their embedded files automatically.

4

Check and run

Run cells in order. After a runtime reset, rerun setup.

Run from the top; rerun setup after a runtime reset.

Verify the interpreter, folder and calculation

```
01 import sys
02 from pathlib import Path
03
04 print(sys.version.split()[0])
05 print(sys.executable)
06 print(Path.cwd())
07 print(3 * 4)
```

1. Check Python 3 and your working folder.
2. The last number should be 12.
3. Weeks 3–10: confirm setup succeeded.

The interpreter and current directory explain many “it works on my machine” problems.

Save the notebook and the files you create

Notebook

Save your edits and explanations. Reopen your copy to confirm they remain.

Generated files

Keep scripts, data and databases that your exercise needs. Colab runtime files are temporary.

Clean rerun

After a runtime reset, rerun setup and preceding cells. Restore your saved artifacts when needed.

A saved notebook is not a backup of every file in its runtime.

An error is information you can use

Name the environment

Your OS or Colab, Python version and the notebook week.

Show the evidence

Input, expected result, observed result and the relevant traceback.

Say what you tried

One attempted fix and its result. Search Issues first; post the successful follow-up.

Report a small example and the exact error, not only “it does not work”.

You are ready when these checks pass

Check	Evidence
Access	You can open the current week and support files.
Execution	A notebook cell runs and reports 12.
Files	Weeks 3–10: the embedded setup reports success.
Persistence	Your saved notebook reopens with your edits.
Help	You can open an Issue with a small example.

Use SETUP.md for the full guide and Issues for shared setup questions.
